ABSTRACT

Data from more than 200 sites in nontidal portions of the Chesapeake Bay were compiled to document annual nutrient and sediment loads and trends for the period 1985 through 1996 as part of the 1997 Reevaluation of the Chesapeake Bay Program goal of reducing nutrient loads 40 percent by the year 2000. Annual loads were estimated by use of the Minimum Variance Unbiased Estimator (MVUE) model at 95 sites with continuous streamflow data. Trends were estimated by use of either the MVUE or the Seasonal Kendall test at 202 sites and are presented in tables in this report. Trends analyzed in nutrient and sediment concentrations were reported as non-streamflow adjusted and streamflow adjusted if possible. Mean yields from the MVUE model and median concentrations from the Seasonal Kendall test were calculated to help facilitate comparisons between basins.

INTRODUCTION

In 1987, the Governors of Pennsylvania, Maryland, and Virginia and the mayor of the District of Columbia signed the Chesapeake Bay Agreement. This agreement called for a 40-percent reduction in the amount of nutrients reaching the Chesapeake Bay by the year 2000. Results from the U.S. Environmental Protection Agency (USEPA) Chesapeake Bay Model indicated improvements in water quality in the Bay sufficient to support living resources could be achieved if the 40-percent nutrient-reduction goal was met. Individual nutrient-reduction goals were established for the major rivers delivering nutrients to the Bay. Progress toward these reduction goals is reevaluated every 5 years (since 1987) by compiling and analyzing water-quality and living-resource data and publishing results in Chesapeake Bay Program progress and reevaluation reports. The 1997 reevaluation effort was to determine if the goals are on target and achievable and determine any changes in water quality and living resources in response to nutrient reduction strategies (NRS) in the Chesapeake Bay Basin.

Two programs, the River Input and Nontidal Synthesis Programs, provide information from the nontidal areas of the Bay. Through the River Input Program, water-quality data is collected, trends in concentration are estimated, and annual loads are estimated at nine stations near the Fall Line¹ (fig. 1). This is done annually by the U.S. Geological Survey (USGS) in cooperation with the Maryland Department of Natural Resources (MdDNR), Virginia Department of Environmental Quality (VaDEQ), and the Metropolitan Washington Council of Governments (WashCOG). Two reports, Zynjuk and Feit (1995) and Johnson and Belval (1998), describe the results of the River Input Program.

¹The "Fall Line" refers to a distinct change in slope generally occurring in a line running southwest to northeast through the Chesapeake Bay Basin. This line generally represents the limit of the tidal areas and tends to coincide where the harder crystalline rocks of the Piedmont Physiographic Province and softer unconsolidated rocks of the Coastal Plain Physiographic Province overlap.

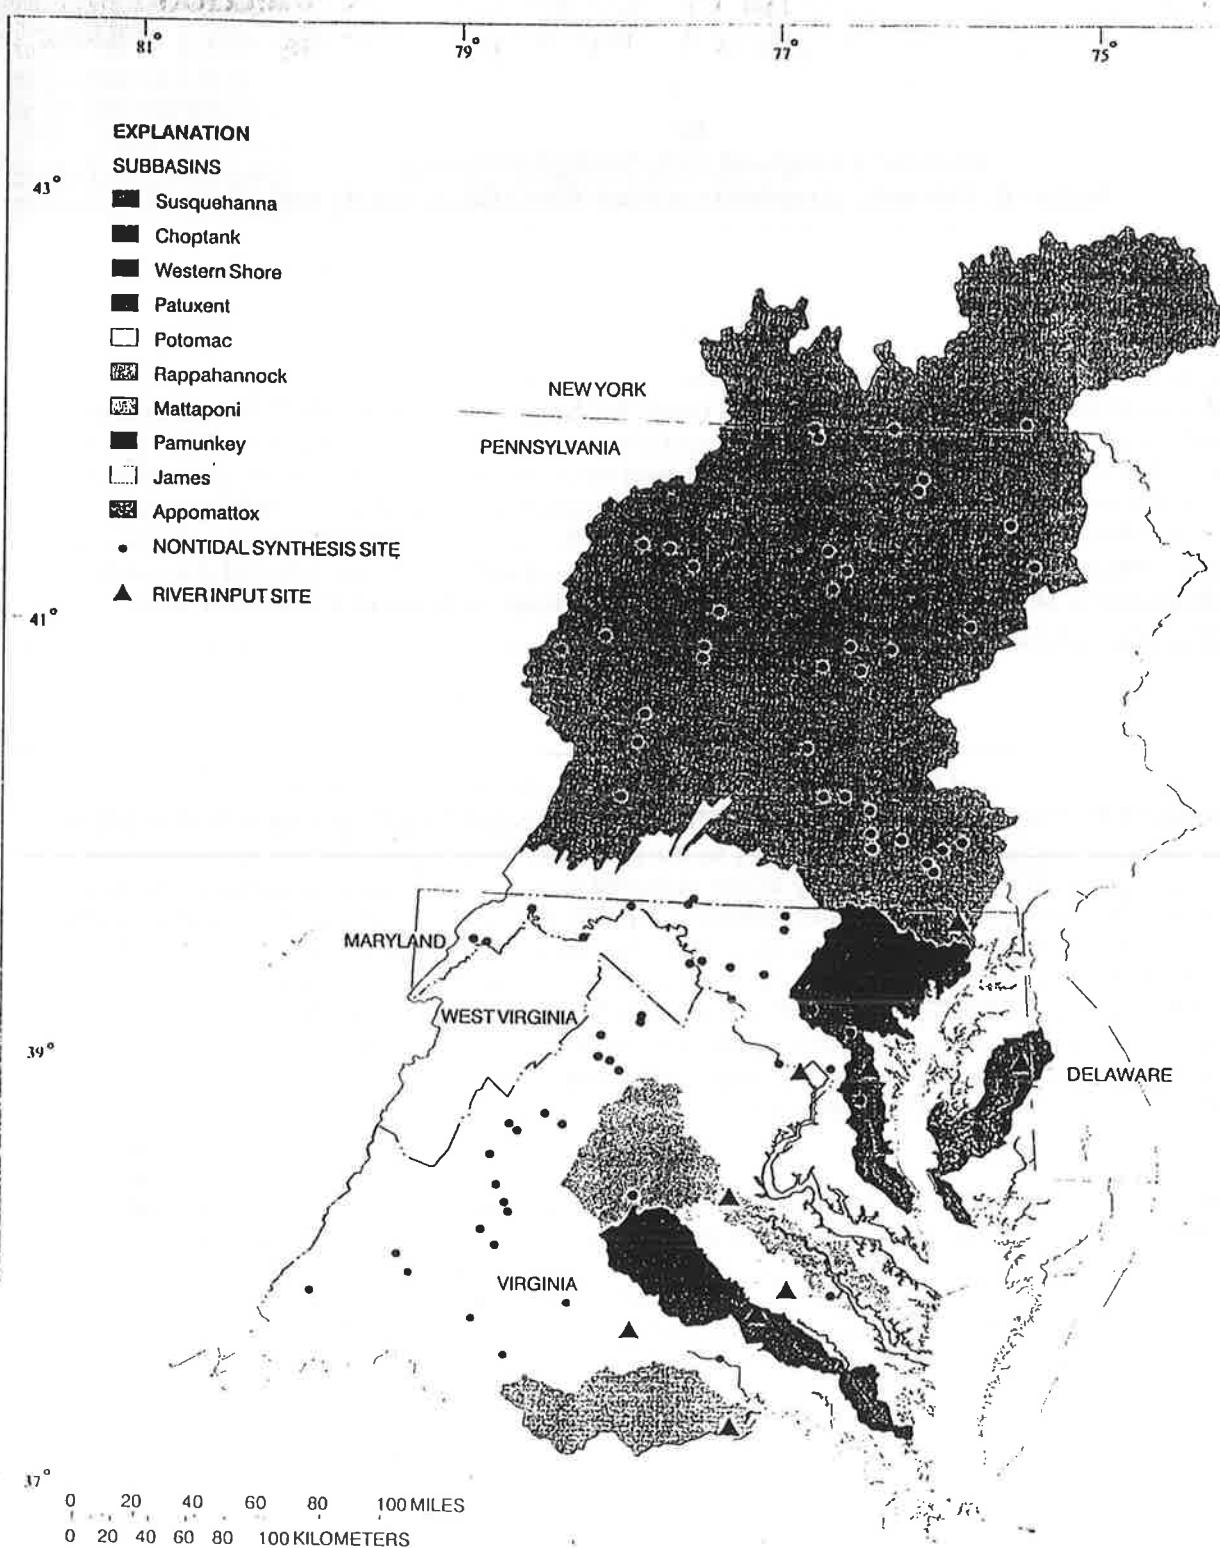

Figure 1. Nine River Input Program sites and 86 Nontidal Synthesis Program sites used for the 1997 reevaluation of loadsites in the Chesapeake Bay Basin.

Currently, through the Nontidal Synthesis Program, water-quality data from 1,329 sites upstream of the Fall Line are synthesized in a single database. The database is comprised of water-quality and streamflow data from sites with a minimum of 3 consecutive years of samples collected between 1972 and 1996. Although water-quality data were collected on a routine basis (usually monthly) at many sites, most of these sites do not have the continuous streamflow record necessary to compute annual loads. In general, water-quality data are not updated nor are estimates of loads and trends completed annually. For the 1997 Reevaluation, water-quality data were used to estimate annual loads and trends at 86 sites in the Nontidal Synthesis Program (fig. 1). Also, as part of the program, at 23 of the 86 sites, the USGS will retrieve concentration data, compute trends in concentrations and loads, and estimate annual loads each year until 2002. Concentration data are retrieved and appended to the database for all current sites in the Nontidal Synthesis Program every 5 years in time for the reevaluations. New sites are added to the database if the site has at least 12 samples collected over 3 continuous years and at least 1 sample from each season (spring, summer, fall, winter).

PURPOSE

For sites in the River Input and Nontidal Synthesis Programs in the Chesapeake Bay Basin, this report (1) documents the methods used to estimate status and trends in concentration and loading data for the 1997 Reevaluation of the nutrient-reduction strategy, (2) presents tabled nutrient and sediment load data, and (3) presents tabled trends in water quality from 1985, when nutrient-reduction strategies were initially implemented in nontidal areas of the Chesapeake Bay Basin, through 1996. Data from this report will be included with water-quality and biological data from the tidal portions of the Bay in the 1997 Chesapeake Bay Program Reevaluation technical report. Annual load data used to compute annual yields is available from the USGS Pennsylvania District and can be obtained by accessing the Pennsylvania District Homepage at <http://wwwpah2o.er.usgs.gov/> and fill out the "Questions" form.

DATA SET CONSTRUCTION

The following section describes the sources of the water-quality and streamflow data, selection of constituents for estimating annual loads and trends, procedures used with censored (data analysis reported below detection limit) data, record length, and procedure for estimating missing constituents.

Data Sources and Preparation

Water-quality concentration and streamflow data were retrieved and compiled into one database from two federal agencies—the USGS, the USEPA—and three state agencies—Pennsylvania Department of Environmental Protection (PaDEP), MdDNR, and VaDEQ. Additional water-quality data were retrieved from the Susquehanna River Basin Commission (SRBC), the Interstate Commission on the Potomac River Basin (ICPRB), and WashCOG. This effort was undertaken to update and extend the time period of the nontidal water-quality database through 1996. Water-quality data previously were compiled and annual loads were estimated for nutrient and sediment from 1972 through 1992 by Langland and others (1995). Site identification numbers, the test analysis type, latitude and longitude, and site name are presented for the 9 River Input Program sites (table 1, at back of report) and the remaining 193 sites in the Nontidal Synthesis Program analyzed as part of the 1997 Chesapeake Bay Program reevaluation (table 2, at back of report). Concentration data obtained from the various sources for inclusion in the nontidal database were quality assured by use of a SAS program that identified suspect remark codes and missing dates and/or times associated with the sample. A cursory visual examination of the data was also done.

Constituents

A total of 36 physical, biological, and chemical water-quality constituents presented in table 3 (at back of report) were retrieved and updated in the database. These constituents included 14 nutrient species, suspended sediment, and total suspended solids. Continuous daily streamflow was retrieved from the USGS water database. The updated nontidal database and the USGS streamflow database provided the input data files for running either the USGS Minimum Variance Unbiased Estimator (MVUE) Model (Cohn and others, 1989), which produced annual loads and streamflow-adjusted trends in concentration, or the Seasonal Kendall test, which produced streamflow-adjusted and non-streamflow-adjusted trends in concentration.

Constituents tested by use of the MVUE model were total nitrogen (TN), dissolved (filtered) kjeldahl nitrogen (TKNf), total (whole) kjeldahl nitrogen (TKNw), total ammonia (TNH₃), dissolved ammonia (DNH₃), total or dissolved nitrate (NO₃), total or dissolved nitrite plus nitrate (NO₂₃), total phosphorus (TP), dissolved phosphorus (DP), dissolved inorganic phosphorus (DIP), suspended sediment (SED), and total suspended solids (TSS).

Constituents tested by use of the Seasonal Kendall trend test included total nitrogen (TN), total nitrate (NO₃) or total nitrite plus nitrate (NO₂₃), total phosphorus (TP), dissolved inorganic phosphorus (DIP), suspended sediment (SED), and total suspended solids (TSS).

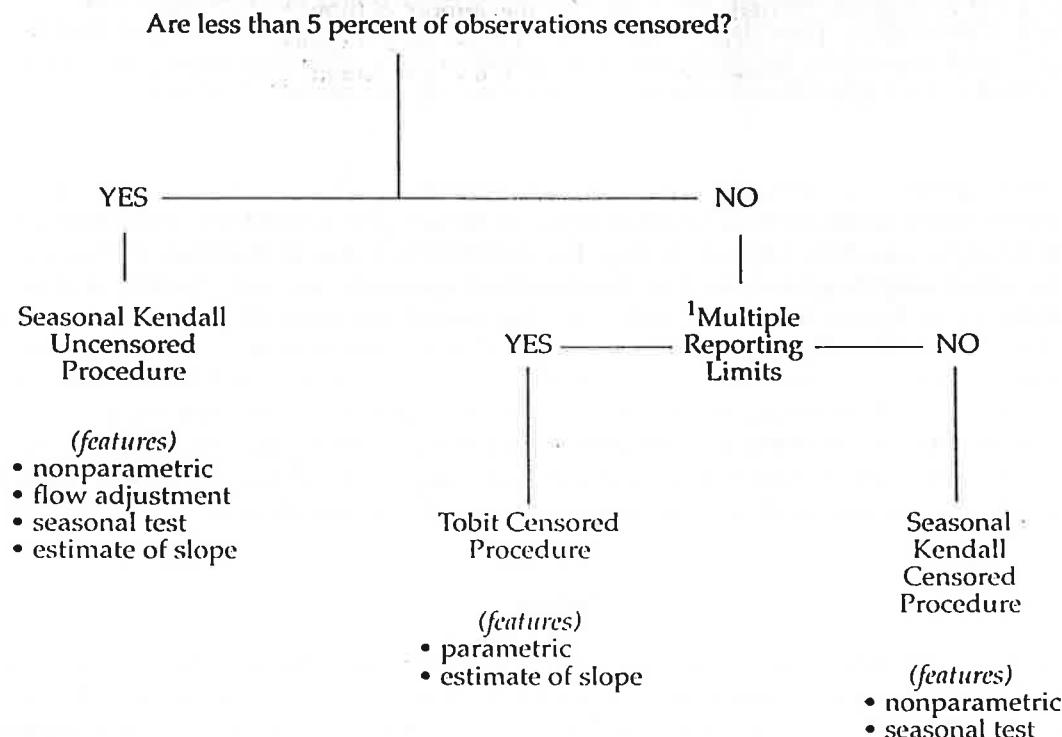

Constituent Estimation

In some data sets, individual records were missing for some constituents. When possible, missing constituents were calculated by use of the various reported species of the constituent. If total nitrogen was missing, an estimated value was obtained by adding total kjeldahl nitrogen (total organic plus total ammonia) and total nitrite plus nitrate nitrogen. If total nitrite plus nitrate nitrogen was missing, the sum of the total nitrite nitrogen and total nitrate nitrogen was used if available. If more than one of the nitrogen species used in calculating total nitrogen was below the detection limit, the estimated value was not determined.

Detection Limits

The presence of a large number of censored values in a data set can adversely affect the estimation of trend slope by not properly calculating a median concentration and correcting the data because of the variation in streamflow. In the MVUE model, values were assigned to the censored data by use of a statistical-based distribution. Cohn and others (1989) describe the use of a Quasi Maximum Likelihood Estimate (QMLE) of the moments of the log normal population from type I censored samples as the method used to assign values to the detection limits.

The following decision tree was presented to the Data Analysis Work Group (DAWG), a workgroup of the Monitoring Subcommittee of the Chesapeake Bay Program, and approved for use with the Seasonal Kendall test for trend. This decision tree is based on current USGS computer programs (Schertz and others, 1991) and work by Helsel and Hirsh (1992).

¹See text for additional explanations.

For the nontidal stations, censored values were assigned a concentration of one half of the detection limit if the censored data were less than 5 percent of the record. In these instances, streamflow adjustment was used if streamflow data were available and the Seasonal Kendall slope estimate and the magnitude (percentage change over time) will be reported. If the data set has between 5 and 20 percent censored data, a single detection limit was used for running the test. The maximum detection limit in the time series was selected as the detection limit to use in the test. All values observed below the maximum detection limit were considered tied and set equal to the maximum detection limit. In these instances, the magnitude of the trend was not reported and streamflow-corrected procedures were not used. For data sets where more than 20 percent of the time-series data is censored, results from the Seasonal Kendall trend test were not reported.

Record Length

For trend results to be most useful for the 1997 Reevaluation, the time series would ideally begin in January 1985 and end in December 1996. Shorter time-series data were acceptable if they met certain criteria. For both the MVUE model and the Seasonal Kendall trend test, this criteria includes a data set containing a minimum of 5 years and 50 monthly samples or 5 years and 20 quarterly samples. The data set must contain instantaneous or daily streamflows for flow correction. Priority dates for the data set are any 5 year or greater time period starting between January 1985 and January 1989 and continuing through 1996.

STREAMFLOW ADJUSTMENT

In tidal areas of the Chesapeake Bay Basin, 10 different streamflow models were evaluated by members of the DAWG to determine the most appropriate lag times (delay in streamflow) and transformations of streamflow. The delay, or lagtime, is the amount of time needed for streamflow to travel from nontidal to tidal areas of the Bay Basin. Because lag times are not critical to virtually all the nontidal areas, the possibility of using a different non-linear streamflow adjustment model existed.

The DAWG agreed to use the LOcally WEighted Scatterplot Smoothing (LOWESS) Procedure to streamflow adjust concentrations for trend testing by use of the Seasonal Kendall test in the nontidal (above the fall line) portion of the Chesapeake Bay. The LOWESS Procedure (Cleveland, 1979) uses distance and residual weighting functions with weighted least squares to minimize the influence of outliers in fitting a smooth (non-linear) line to the data. The smoothness factor (f) varies from 0 to 1, is specified by the user, and usually ranges between 0.3 and 0.7; an increase in f corresponds to a smoother line. The USGS completed a nationwide study (Lanfear and Alexander, 1990) in which more than 50,000 trend tests were performed at nearly 3,000 stations for more than 200 constituents. This study indicated that an f value of 0.5 gave a reasonably good fit to the data without removing important features of the concentration-streamflow relation or producing very abrupt changes in local slope and found this to be appropriate for the non-conservative constituents of concern in the Chesapeake Bay.

STATUS

To facilitate comparison of current water-quality conditions between basins, either a 3-year mean yield (MVUE) or 3-year median concentration (Seasonal Kendall) was calculated for all possible constituents from 139 of the 202 sites presented in this report. Mean yields and median concentrations were reported only where the data record started no later than 1989 and did not end prior to 1994.

Yield

The status of current annual loads and yields using the MVUE was assessed for different constituents at 32 sites—9 from the River Input Program and 23 sites upstream of the River Input sites, a subset of the Nontidal Synthesis Program. This assessment was based on a 3-year mean yield (referred to as status yield) for the years 1994, 1995, and 1996 or the last 3 years of record if 1994-96 was not available. The status yield was determined as follows:

- compile all status yield data by station and constituent
- determine the 5th and 95th percentile for each constituent
- subtract the 95 percentile value from each status yield for each constituent—(a)
- subtract the 5th percentile from the 95th percentile values for each constituent—(b)
- divide the result from (a) by the result from (b) and multiply by 100.

The above procedure transforms the status yields from each basin and constituent into percentages between 0 and 100. The percentages were subtracted from 100 to allow a simple comparison between basins, because the lower the percentage, the lower the yield. Status yields and percentages for the 32 sites are presented in table 4 (at back of report).

Concentration

The status of current water-quality conditions using the Seasonal Kendall test was determined by site and constituent at an additional 107 non-MVUE sites. This status concentration was based on the median concentration for the period 1994-96 or the last 3 years of record if 1994-96 was not available and based on analysis of all non-streamflow adjusted concentrations at the site. Non-streamflow adjusted and streamflow adjusted (if data were available) results are presented in table 5 (at back of report).

TRENDS

Two tests, the MVUE model and the Seasonal Kendall test, were used to estimate trends. The MVUE model was used where water-quality and daily streamflow data existed to compute trends and annual loads. The Seasonal Kendall test was used where daily streamflow did not exist or the MVUE model could not calibrate and estimate a trend because of either incomplete water-quality data or streamflow files.

Minimum Variance Unbiased Estimator (MVUE)

Streamflow adjusted trends and statistics were estimated for the period 1985 through 1996 for the 9 River Input Program sites and 23 sites upstream of the River Input sites (table 4, at back of report). The results in table 4 are corrected to account for streamflow and seasonality. Statistics include probability (p) and slope (b) for all constituents. Where p is less than 0.05 (indicating a significant trend), the trend direction and magnitude (percentage change in trend) for the time period are always given. The magnitude and slope are re-transformed from log space. The magnitude for the period is determined from the equation $(e^{(B3 \times t)} - 1) \times 100$, where e^x is the anti-log of the natural log, B3 is the DECTIME regression coefficient from the MVUE model, and t is the number of years for the time period examined. The slope is determined from $(e^B B3) - 1$. Trend results for an additional 65 sites, part of the Nontidal Synthesis Program, from other areas of the Bay Basin of varying dates are presented in table 6 (at back of report).

Seasonal Kendall

Trend statistics are presented for the uncorrected monthly median concentrations and streamflow-corrected concentrations (if available) in table 4. For the uncorrected concentrations, statistics include the probability (p) and slope (b) for all constituents. Where p was significant (less than 0.01 for non-streamflow-adjusted trends and less than 0.05 for streamflow-adjusted trends), the trend direction, the base median (BM), period of record median (POR), status median, magnitude using the DAWG method (percentage change BM), and magnitude using the Sen estimate (percentage change POR) were included (Helsel and Hirsch, 1992). The BM is defined as the median of the monthly medians for the first 24 months of the data record. The POR is defined as the median of the monthly medians for the entire time series. The magnitude according to the DAWG method is defined as b times the number of years of data times 100 divided by BM. The magnitude using the Theil slope estimate (Helsel and Hirsh, 1992) is defined as b divided by POR times 100.

For the streamflow-adjusted concentrations, the same statistics were presented as listed above for the uncorrected concentrations. However, streamflow correction produces residuals from a concentration-streamflow relation and must be transformed back to "real" space to determine values that are meaningful. Therefore, the streamflow-adjusted BM was determined by adding the POR to each residual. Likewise, the streamflow-adjusted POR was determined by adding the uncorrected POR to each residual. The streamflow-adjusted BM and POR were then used to calculate the magnitudes of trend. Because of a lack of streamflow data at many sites, results for streamflow correction from the Seasonal Kendall test are limited.

Table 3. List of constituents contained in U.S. Geological Survey nontidal water-quality database, 1972-96
 [ft³/sec, cubic feet per second; mg/L, milligrams per liter; µg/L, micrograms per liter]

Constituent code	Data description
STAID	Station number
SNAME	Station name
AGENCY	Collection agency code
DATE	Date of sample collection
TIME	Time of sample collection
LAT	Latitude
LONG	Longitude
HUC	Hydrologic unit code
00010	Water temperature in degrees Celsius
00060	Daily mean discharge, in ft ³ /sec
00061	Instantaneous discharge, in ft ³ /sec
00065	Stream stage, in feet
00076	Turbidity
00095	Specific conductance in micromhos per centimeter
00300	Dissolved oxygen in mg/L
00400	pH, in units
00410	Total alkalinity as CaCO ₃ , in mg/L
00530	Total suspended solids at 105 degrees Celsius, in mg/L
00600	Total nitrogen as N, in mg/L
00608	Dissolved ammonia as N, in mg/L
00610	Total ammonia as N, in mg/L
00613	Dissolved nitrite as N, in mg/L
00615	Total nitrite as N, in mg/L
00618	Dissolved nitrate as N, in mg/L
00620	Total nitrate as N, in mg/L
00623	Dissolved ammonia plus organic nitrogen as N, in mg/L
00625	Total ammonia plus organic nitrogen as N, in mg/L
00630	Total nitrate plus nitrite as N, in mg/L
00631	Dissolved nitrate plus nitrite as N, in mg/L
00665	Total phosphorus as P, in mg/L
00666	Dissolved phosphorus as P, in mg/L
00671	Dissolved inorganic phosphorus as P, in mg/L
00680	Total organic carbon as C, in mg/L
00681	Dissolved organic carbon as C, in mg/L
00900	Hardness as CaCO ₃ , in mg/L
00915	Dissolved calcium as Ca, in mg/L
00925	Dissolved magnesium as Mg, in mg/L
00930	Dissolved sodium as Na, in mg/L
00935	Dissolved potassium as K, in mg/L
00940	Dissolved chlorine as Cl, in mg/L
00945	Dissolved sulfate as SO ₄ , in mg/L
00955	Silica as SiO ₂ , in mg/L
32211	Chlorophyll <i>a</i> , in µg/L
32231	Chlorophyll <i>b</i> , in µg/L
32232	Chlorophyll <i>c</i> , in µg/L
49954	Algal dry mass
80154	Total suspended sediment, in mg/L

Table 4. Statistical data and yields for 9 River Input Program sites and 23 Nontidal Program Synthesis sites listed by streamflow site, load site, and data-collection agency using the Minimum Variance Unbiased Estimator (MVUE) model (Cohn and others, 1989)

[Agency - USGS, U.S. Geological Survey; SRBC, Susquehanna River Basin Commission; PaDEP, Pennsylvania Department of Environmental Protection; MdDNR, Maryland Department of Natural Resources; VaDEQ, Virginia Department of Environmental Quality; WashCOG, Metropolitan Washington Council of Governments.

Parameters - 00530, total suspended solids (TSS); 00600, total nitrogen (TN); 00608, dissolved ammonia (DNH₄); 00610, total ammonia (TNH₄); 00618, dissolved nitrate (DNO₃); 00620, total nitrate (TNO₃); 00623, dissolved ammonia plus organic nitrogen (DKJD); 00625, total ammonia plus organic nitrogen (TKJD); 00630, total nitrite plus nitrate nitrogen (TNO₃₂); 00631, dissolved nitrite plus nitrate nitrogen (DNO₃₂); 00665, total phosphorus (TP); 00666, dissolved phosphorus (DP); 00671, dissolved inorganic phosphorus (DIP); and 80154, suspended sediment (SED).

Statistics - decline coefficient, one of the modeled regression coefficients; p-value, measure of significance of regressor; b, regression slope; direction, up or down; percentage change, change for indicated time period; status yield, mean of last 3 years annual yields; percentage yield, each status yield divided by mean status yield for all sites with same constituent, ranges from 0-100 percent, the lower the percentage yield, the lower the status yield; shaded areas are significant at 95-percent confidence level; --, not applicable or insufficient data.]

Streamflow site identification number	Load site identification number	Agency	Constituent code	Time period of trend	Statistics from MVUE for decline coefficient			Status yield (pounds per acre)

* Denotes River Input Program site.

Table 5. Seasonal Kendall trend results for selected sites and constituents in the Nontidal Synthesis Program for calendar years 1985 through 1996
 [POR, period of record median; Base median (BM), median for the first 24 months of record; status median, median for the last 36 months of record; Season, M- monthly, B- quarterly, Q- bimonthly; p-value, value of significance; percentage change, trend expressed as a percent based on the length of the time period tested; the slope, and original period of record median and base median; --, no data; n/a, not applicable because more than 20 percent of data values exceeded the detection limit; shaded areas represent significant trends at 90-percent confidence level for unadjusted concentrations and 95-percent confidence level for streamflow-adjusted concentrations]

Site identification number	Number of samples	Period of record median (POR)	Base median (BM)	Status median	Season	p-value	Slope (units/year)	Unadjusted for streamflow concentration			Streamflow-adjusted concentration							
								Per-centage change (POR median)	Per-centage change (BM)	Per-centage less than detection	Period of record median (POR)	Base median	Status median	Season	p-value	Slope (units/year)	Per-centage change (POR median)	Per-centage change (BM)

Table 6. Statistical data for additional sites, dates, and constituents in the Nontidal Data Synthesis Program in the Chesapeake Bay Basin listed by streamflow site, load site, and data-collection agency using the Minimum Variance Unbiased Estimator (MVUE) model (Cohn and others, 1989)

[Agency - PaDEP, Pennsylvania Department of Environmental Protection; USGS, U.S. Geological Survey; MdDNR, Maryland Department of Natural Resources; WashCOG, Metropolitan Washington Council of Governments; VaDEQ, Virginia Department of Environmental Quality.

Constituents - 00530, total suspended solids; 00600, total nitrogen; 00608, dissolved ammonia; 00610, total ammonia; 00618, dissolved nitrate; 00620, total nitrate; 00623, dissolved ammonia plus organic nitrogen; 00625, total ammonia plus organic nitrogen; 00630, total nitrite plus nitrate nitrogen; 00631, dissolved nitrite plus nitrate nitrogen; 00665, total phosphorus; 00666, dissolved phosphorus; 00671, dissolved inorganic phosphorus.

Statistics - p-value, measure of significance of regression; slope (b), regression slope; percentage change, change in load for indicated time period; shaded areas represent significant results at 95-percent confidence level]
